Blair (WB) medium. Tests were conducted on 194 samples of feces of typhoid or suspected typhoid and on 33 samples of recuperative or bacteriological isolating patients. Inoculations from enriched media were made 18-20, 48 hours, and 7 days after cultivation. In 51 positive cases, inoculations from MK medium were made in 5-8 hours. Altogether 90 positive results were obtained; from the medium with 0.4% sodium selenite, positive results were obtained in 91.1% of cases; from the medium with 0.2% sodium selenite in 87.7%, from MK medium in 74.4%, and from broth in 57.7%. Inoculation directly on WB medium produced 86.6% viability. Optimal period for cultivation on MK medium was 5-8 hours, on other enriched media 18-20 hours. The authors recommend inoculation on media

TOPIC TAGS: antibody, virus disease, blood serum, man, blood chemistry

ABSTRACT: In a study of parainfluenza hemagglutination inhibition antibodies carried out on 500 human serum samples, the authors found that the most widespread type determining the highest antibody level in the population is the type 3. Next are type 1 (Copenhagen and Sendai), and less frequent is type 2 (CA). Ecaterina Ghenescu performed technical work. The authors thank Doctor M. Gaicu and Eugenia Lungu for preparing the tissue cultures. Orig. art. has: 2 figures and 2 tables. [Based on authors' Eng. abst.] [JPRS: 32,913]

2313. Graphical Classification of Valves. S. J. Zilitinkewitsch.
Phys. Zeits. d. Sowjetunion, 3, 6, pp. 408-416, 1933. In German.
A graphical method is described for representing the various features of
valves on a single diagram. The diagram is essentially a network with four
axes inclined to one another at 45°, the four axes representing (a) amplifica-
tion factor, (b) resistance, (c) slope of characteristic and (d) "gondions,"
the latter being the product of amplification factor and slope of character-
istic. Classification on the lines indicated is stated to simplify the com-
parison of one valve with another and to facilitate the selection of a valve
for a particular purpose. A diagram is given for a large number of Russian,
American and German valves. A. W.

2218. Theory of Rectifier Operation on Ohmic Resistance and Capacitance. S. Zilfinkevich. *Zhur. Fiz., U.S.S.R.* 6, 2, pp. 94-124, 1938. In German.—The author presents a general treatment of the theory of rectifier operation on an ohmic resistance R with a smoothing capacitance C , and establishes the relations between the rectified voltage, the crest value of the alternating voltage, and the value of the product RC . All the electrical characteristics of the rectifier are examined and formulae are established, of which those hitherto usual are special cases. From these results, the theory of the conversion of d.c. to a.c. by electronic valves can be deduced. A numerical example is given to illustrate the application of the general theory to concrete problems, and the effect on the rectification phenomena of altering the product RC is investigated. Curves covering the range from zero capacitance ($RC = 0$) to infinite resistance (no load, $RC = \infty$) show that increasing the product RC , or the smoothing capacitance with constant R , improves the operating conditions in all respects excepting the factors dependent on the maximum current impulse. TITLE: A TV Device for Controlling Cross-Section of Material Being Drawn
(Televisionnyy pribor dlya kontrolya poperechnykh razmerov protyagivayemogo
materiala)

PERIODICAL: Izv. vyssh. uchebn. zavedeniy. Priborostroyeniye, 1958,
Nr 1, pp 12-22

ABSTRACT: The authors suggest a device for continuous checking of very small
cross-sections of materials being drawn: metal wires, films and nonmetal
filaments, bands. In the first case, measurement of the resistance of moving
sections of wire is a convenient method. However, fluctuating contact
resistance values cause serious difficulties. For that reason, a special auto-
compensation method is used which permits excluding the fluctuating potential
differences due to contacts from the instrument readings. When slip contacts

Card 1/2

SOV/112-59-3-5473

A TV Device for Controlling Cross-Section of Material Being Drawn

are undesirable or impossible (e.g., in the case of a very thin wire or in the case of directly determining the cross-sectional area of the material being drawn), a capacitive method of measurement is feasible. To control the cross-dimensions of a moving conductor or nonconducting material, it is expedient to use a method based on the dependence of a phototube electron current on the luminous flux falling upon its cathode; the value of the luminous flux is maintained strictly proportional to the diameter of the material being measured. The new TV-type method is a further development of the photoelectric method; it ensures a particularly high accuracy in determining the cross-sections of the controlled materials. The new instrument built by the Chair of Radio Engineering, Leningradskiy institut tochnoy mekhaniki i optiki (Leningrad Institute of Precise Mechanics and Optics), is considered in detail, as well as its characteristics, the TV-method principles, and drawing-mechanism controls. Eight illustrations. Bibliography: 3 items.

A Device for Noncontact Measurements of Resistance Irregularities
of Moving Wires

PERIODICAL:

Izvestiya vysshikh uchebnykh zavodeni, Priborostroyeniye, 1959,
Nr 1, pp 3-12 (USSR)

ABSTRACT:

At the Leningrad Institute of Precision Mechanics and Optics a device was developed for measuring resistance irregularities of wires of 20-150 micron diameter moving at speeds of 1-20 m/min without damaging the insulation. The accuracy of the measurements are $\pm 0.5\%$ of the resistance of a measured length. The device consists of two basic sections: a) The spooling section and b) the measuring section. In fig.1, a photograph of both sections is shown. The kinematic system of the spooling section is shown in diagram (Fig.2). A D0-50 (1425 rpm) motor is used for driving the spools in combination with a photo-electric tension con-

Card 1/3

66208

SOV/146-59-1-1/21

A Device for Noncontact Measurements of Resistance Irregularities of Moving Wires

trol unit which keeps the tension of the wire to be measured at a pre-set level. A counter indicates the length of wire wound from one spool to the other. The measuring section consists of a frequency modulated generator (2 Mc), an indicator unit, a self-recorder, an automation unit, the power supply unit and the measuring unit. The complete circuit diagram of the measuring section is shown in fig.6 (insert). The wire to be measured passes over two current-conducting capacitance electrodes, as shown in fig.4. These electrodes may be considered as capacitors in combination with the wire to be measured. The air gap between the wire and the electrodes as well as insulation of the wire serve as a dielectric. The electrodes are connected to the generator forming an oscillatory circuit with the inductance L. With resonance, the magnitude of current flowing thru the measuring circuit will be at a maximum. With a given voltage, it will depend only on the resistance. By recording the maximum current value, the changes in the resistance of the wire to be measured

Card 2/3

4

66208 146-59-1-1/21

A Device for Noncontact Measurements of Resistance Irregularities of Moving Wires

may be judged. The generator is tuned in such a manner that its central frequency is equal or close to the natural frequency of the measuring circuit. The output voltage of the generator is stabilized by a feedback circuit. The direct voltage at the anode of the oscillator tube is changed depending upon the hf voltage at the oscillator outlet. The power supply unit consists of six different rectifier circuits. There are 1 photograph, 3 circuit diagrams, 2 diagrams and 2 graphs.

Izvestiya vysshikh uchebnykh zavedeniy - radiotekhnika, 1959, Vol 2, Nr 1, pp 114-117 (USSR)

ABSTRACT:

At the Kafedra radiotekhniki Leningradskogo instituta tochnoy mehaniki i optiki (Chair of Radio Engineering of the Leningrad Institute of Precision Mechanics and Optics), in cooperation with specialists from the Faculty of Precision Mechanics, a device was developed for noncontact uniformity of resistance measurements of insulated, thin, high-resistance wire during the coil-winding process. The advantages of this device are that the resistance can be measured without damaging the insulation

Card 1/4

A Device for Noncontact Uniformity of Resistance Measurements of
Insulated, Thin, High-Resistance Wires During the Coil-Winding
Process

stress during the measuring process with a high precision. The moving wire is connected to the measuring circuit by capacitive coupling, which is achieved by two metal rollers. The effective length of the measured wire sections is 920 mm. The HF generator produces frequency-modulated electromagnetic oscillations at frequencies ranging from 1.5 to 3.5 mc. The oscillation amplitude of this generator is kept constant with a high accuracy over the entire range of the modulated frequencies. The indicator unit permits the visual observation of the resistance values. In case the latter are below or above a pre-set level, the self-recorder is switched on automatically, together with an acoustical and optical signal. A counter records the length of the wire processed. The measurement errors are 0.5% of the resistance of the measured section.

TITLE:

The Classification of Basic Rectification Circuits

PERIODICAL:

Izvestiya vysshikh uchebnykh zavedeniy, Priborostroyeniye,
1959, Nr 4, pp 8-16 (USSR)

ABSTRACT:

In this paper the author presents a classification of existing rectifier circuits. In his opinion, the existing terminology used for describing rectifier circuits is inaccurate and sometimes contradictory. This is caused by the fact that during the past numerous engineers, radio amateurs, etc, developed rectifier circuits and used their own terminology for describing the latter. The author starts the classification with definitions of 1) a m-phase rectifier feed circuit, 2) a n-phase rectifier circuit, 3) a single-direction rectification, 4) two-direction rectification, and 5) number of rectification ways (chislo taktov vypryamleniya). The latter are equal to the number of single-direction working current pulses entering the rectifier.

Card 1/4

SOV/146-58-4-2/22

The Classification of Basic Rectification Circuits

two- (six-, six-) way bridge rectifier circuit (mostovaya skhema odnofaznogo /trekhfaznogo, shestifaznogo/ shestitaktnogo /sheshtitaktnogo/ vypryamleniya). III - 2 is also called Larionov circuit. I - 3 voltage double rectifier circuit (of Cockcroft and Walton) = single-way voltage doubler rectifier circuit (skhema odnotaktnogo vypryamleniya s udvoyeniyem napryazheniya). I - 4 convectional voltage loubler rectifier circuit (skhema Greynakhera-Latura) = two-way voltage doubler rectifier circuit (skhema dvukhtaktnogo vypryamleniya s udvoyeniyem napryazheniya). I - 5 multiple voltage multiplier rectifier circuit (of Cockcroft and Walton) = single-way rectifier circuit with multiple voltage multiplication (skhema odnotaktnogo vypryamleniya s mnogokratnym umnozheniyem napryazheniya). The author presents the 10 circuit diagrams for the aforementioned rectifier circuits, repeating both, the conventional and his proposed classification designation. In addition there are two classification tables. One is arranged according to single, bi-, three- and six-phase

TITLE: Device for measuring secondary radiation, operating with a
reflecting clystron-autodyne

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Priborostroyeniye,
v. 4, no. 2, 1961, 3-9

TEXT: This article describes a device developed at the kafedra radio-
tekhniki Leningradskogo instituta tochnoy mehaniki i optiki (Department
of Radio Engineering of the Leningrad Institute of Precision Mechanics and
Optics), where the problem of replacing reception- and transmission
channels was radically solved through application of the autodyne
principle by means of a reflecting clystron, the latter serving not only
for generating the emitted oscillations, but also for detecting oscilla-
tions which are received as a consequence of secondary radiation of the
objects concerned. When the object to be investigated is shifted in the
radiation field of the device, the reflected high-frequency energy acts on

Device for measuring...

the clystron-autodyne and generates at its output resistance a voltage with Doppler frequency proportional to the energy of the secondary radiant flux. The device for measuring the parameters of secondary-radiation sources was built according to the block diagram shown in Fig. 2. It contains the following main components: 1) the measuring channel consisting of the clystron generator, a directional coupler, an antenna and a measuring amplifier; 2) a system for controlling the clystron-autodyne sensitivity, consisting of a generator for sensitivity control, the clystron-autodyne, a measuring amplifier and a sensitivity-control indicator; 3) a system for controlling the autodyne-generator power output, consisting of a directional coupler, a detector, an amplifier and an indicator for output control; 4) a system for recording the movement parameters of the model, consisting of a device for recording the rotation (electronic counter with rotation indicator) and a velocity recording device (velocity pickup and -indicator); 5) a control panel intended for switching on and adjusting the entire measuring device as well as other devices representing part of the measuring complex, and 6) the current sources. The clystron-autodyne is connected with the antenna and serves for generation, reception and autodyne detecting. In the presence of a

moving object in the radiation field of the device, the reflected energy passes to the antenna and acts on the clystron autodyne, thus causing working conditions corresponding to the change of its outer high-frequency load. In this way, an intelligence signal with Doppler frequency is generated in the load resistance of the clystron-resonator circuit. For easier calculation of the autodyne-generator reaction on changes of the outer high-frequency load, the notion of sensitivity is introduced with the aid of which the ratio of the signal voltage obtained at the load resistance of the autodyne, to the corresponding change of the outer conductivity of the clystron is denoted, i.e.,

$$S = \frac{U_{sign}}{\Delta Y_{ext}/Y_{ext}}$$

The analysis of the expression for the sensitivity shows that this strongly depends on the selection of the operating point within the generation zone in the reflecting clystron. The approximate dependence of the sensitivity along the generation zone is given graphically in Fig. 3, from which it can be seen that maximum sensitivity during operation can be obtained at the zone borders, the working conditions of the generator-autodyne being, however, rendered very unstable thereby. For an

increase of the dynamic range of the device and the stability of its operation, the operating point of the clystron within the generation zone must be selected with a sensitivity of 0.8 to 0.9 of the maximum value. The noise level of the device lies at 1 mv, warranting at least equal sensitivity for the receiver channel as for the direct-amplifier-receiver. The voltage pulsation amplitude was reduced by means of suitable filters and a high degree of stability of the supply voltages; a further measure for increasing the sensitivity was the selection of the working frequency band of the measuring channel. Fig. 5 shows a simplified diagram for sensitivity control. The device described mainly serves for measuring the secondary radiation energy, which is required for measuring reflection coefficients of surfaces of different shape, composition and structure, for measuring secondary radiation diagrams of various objects, etc. It can also be used for contactless measurements of displacements and vibrations with small amplitudes, for measuring vibrations with arbitrary maximum frequencies, etc. This study was recommended by the Department of Radio Engineering of the Association. There are 5 figures and 4 Soviet-bloc references.

TITLE: An instrument for measuring the resistance of non-insulated wires and its degree of uniformity with respect to length

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Priborostroyeniye, v. 5, no. 5, 1962, 21-29

TEXT: The authors describe a device for securing the measurement of an absolute value of the resistance of consecutive segments of moving wires from 20 microns to 0.3 mm in diameter, as well as its uniformity. The error does not exceed $\pm 0.1\%$. The electrical measuring device is described in detail. The instrument has two rewinding devices, one for wire diameters 0.02 to 0.1 mm, velocities 1 to 25 m/min and tensions 5 to 100 g; the other for 0.1 to 0.3, 2 to 50 m/min and 100 to 700 g; the latter is described. There are 5 figures and 1 table.

TITLE: Tests of high-power carburized cathodes under conditions of repeated gaseous flashes

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Priborostroyeniye, v. 5, no. 4, 1962, 3-10

TEXT: The last decade has witnessed the successful introduction of cathodes of carburized thoriated tungsten in high-power sealed oscillator tubes. To assess the possibility of extending their use to highpower dismountable tubes, samples of such cathodes 2 x 60 mm² have been studied in sealed water-cooled standard-design diodes connected to ionization manometers and operated at 500 V, 1.5 - 2 A, with 46 - 48 A heater current; the more frequent sporadic release of sorbed gas as occurs in dismountable systems is simulated by breaking air-filled bulbs 4.5 cm³, situated in side branches of the diode envelope. The breaking of each little bulb causes a flash followed by a drastic current decrease (90 - 95% loss of

emissivity). Normal emission, together with the initial vacuum conditions, is restored automatically after $2\frac{1}{2}$ to 9 hours, the restoring time depending on the pressure increase that causes the flash and the state of degassing of the apparatus. Similar experiments have been carried out in diodes connected to exhaust units. Emissivity can be restored, in this case, in 15 min. by means of thermal activation of the cathode. The restoring of the initial vacuum is slower and, after an intense gas flash ($> 10^{-3}$ mm Hg) or after repeated flashes, requires that the whole diode be subject to thermal treatment. There are 3 figures and 3 tables.

TITLE: Performance of carbide power cathodes in reduced vacuum

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Priborostroyeniye, v. 5, no. 5, 1962, 3-7

TEXT: The authors present the results of experiments carried out in 1961 at the Kafedra radiotekhniki Leningradskogo instituta tochny mekhaniki i optiki (Department of Radio Engineering of the Leningrad Institute of Precision Mechanics and Optics) with the view to determining the lifetime of carbide power cathodes operating under the conditions of reduced vacuum. A special experimental type of power diode was used for this purpose. The pressure was regulated by means of a specially designed valve - a gas generator ГУ-50 (GU-50), joined to the diode together with a manometer valve ЛМ-2 (LM-2). The gas pressure in the gas generator was regulated by activated carbon, acting as gas absorber. The carbon was heated by the filament of the GU-50 valve without oxide coating. The pressure
